

# Voyage en 4 étapes vers le centre de la Terre

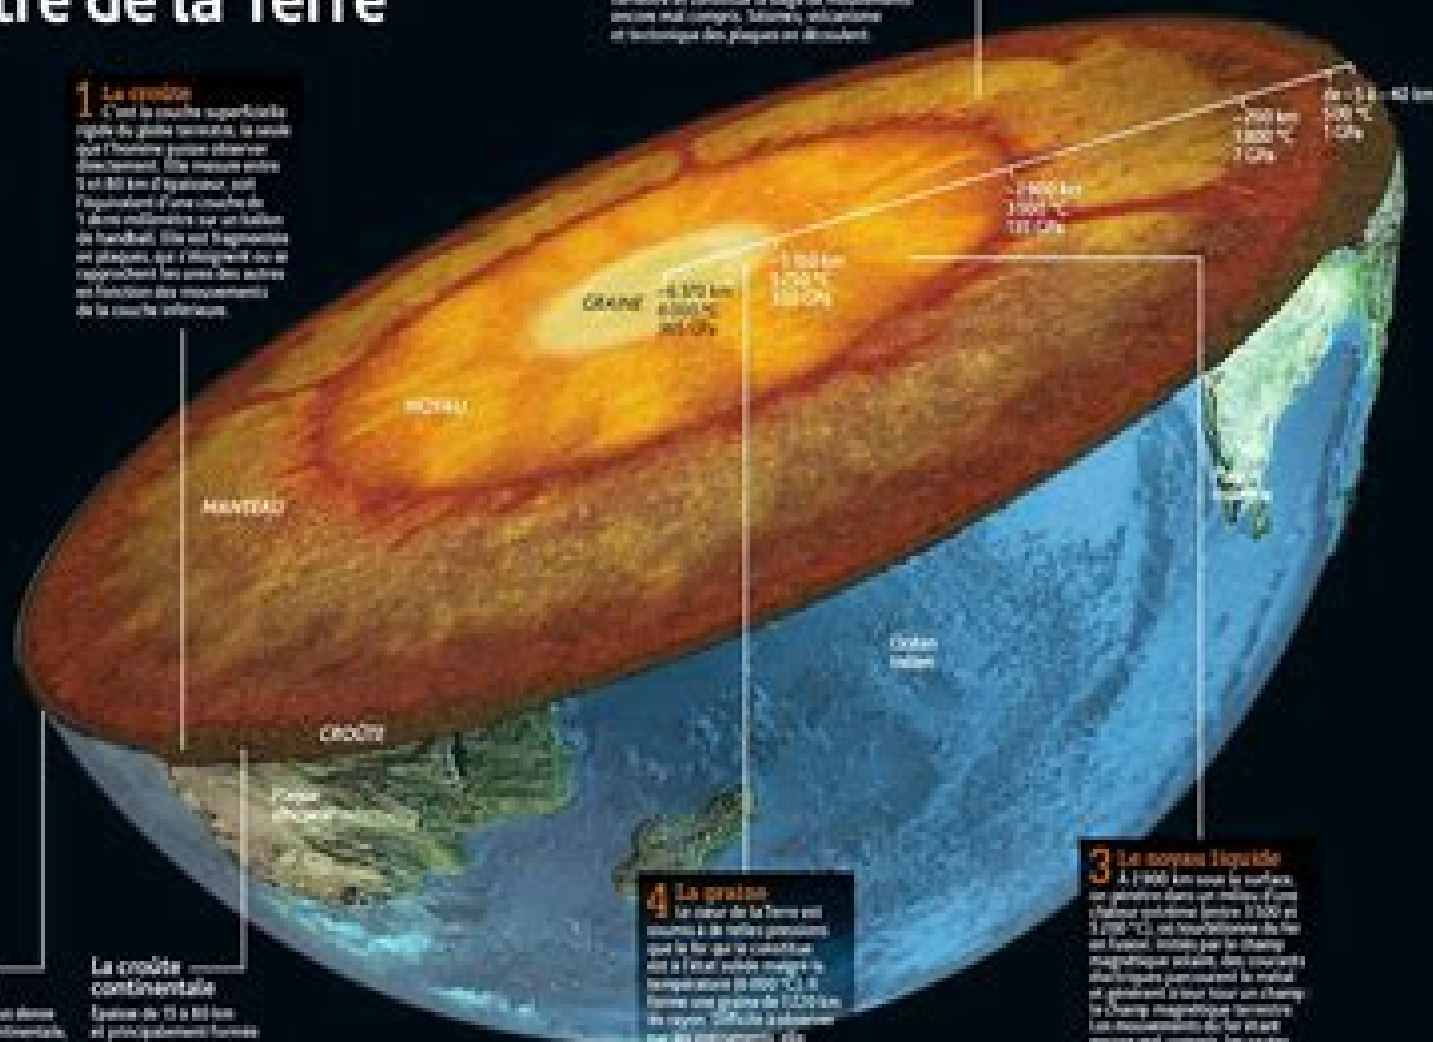

Sur les photos satellites qui nous sont aujourd'hui si familières, on la voit flotter, toute bleue dans le noir du vide spatial, toute enveloppée de son cocon de nuages blancs. Elle nous apparaît alors comme une oasis humide, tempérée, accueillante, immuable et incroyablement calme. Pourtant... sous sa surface paisible, la Terre n'est qu'un monstrueux bouillir d'énergie, brillante et tumultueuse. Sous sa fine croûte de quelques dizaines de kilomètres [1], le manteau brasse en permanence des milliards de milliards de tonnes de roches [2], qui rencontrent en profondeur un océan de fer en fusion porté à plusieurs milliers de degrés Celsius: le noyau [3]. Enfin, au cœur de ce noyau, à l'hypercentre de la Terre, trône la graine [4], une boule solide de fer cristallin, écrasée par la pression monumentale des couches supérieures qui pèsent sur elle. Cette structure en couches roses, les scientifiques l'ont peu à peu dévoilée, notamment grâce à la sismologie (voir p. 102). Mais les mécanismes qui créent chacune des couches concentriques sont, encore en grande partie mystérieux. Et il reste aux chercheurs beaucoup à accomplir et beaucoup à comprendre pour prétendre avoir saisi la formation de notre planète.

## 1 La croûte

C'est la couche superficielle rigide du globe terrestre, la seule que l'homme puisse observer directement. Elle mesure entre 1 et 60 km d'épaisseur, soit l'équivalent d'une couche de 1 dm de collimateur sur un ballon de football. Elle est fragmentée en plaques, qui s'écarteront ou se rapprocheront les unes des autres en fonction des mouvements de la couche inférieure.

## 2 La mantasse

C'est la couche la plus chaude de la planète, la majeure partie de son volume de poids, elle représente 84 % de la masse de la Terre. Étendue d'environ 1 700 km, elle supporte la croûte terrestre et constitue le siège de mouvements encore mal compris. Malgré une pression et une température des plaques en équilibre.

### La croûte océanique

Plus fine mais plus dense que la croûte continentale, elle est composée de roches basaltiques, elle mesure de 1 à 7 km d'épaisseur.

### La croûte continentale

Épaisse de 10 à 60 km et principalement formée de roches granitiques, c'est elle qui constitue les continents.

## 4 La graine

Le cœur de la Terre est constitué de fer pur, qui se cristallise car la température est inférieure à la température de fusion du fer. À l'intérieur, il y a une graine de 1 200 km de rayon. Difficile à observer par les instruments, elle donne lieu à des controverses scientifiques récentes.

## 3 Le noyau liquide

À 1 700 km sous la surface, on pénètre dans un océan d'une chaleur extrême (entre 1 000 et 1 700 °C), un océan d'acier en fusion. Malgré la chaleur, le noyau externe est liquide, car la température est inférieure à la température de fusion du fer. Les mouvements de ce noyau créent le champ magnétique terrestre. Les mouvements de ce noyau sont encore mal compris, les autres aspects du champ magnétique restent difficiles à expliquer.
