

Selection and Speciation

How can changes in a population result in the formation of a new species?

Why?

Have you ever wondered how the great diversity of life on Earth has come about or how a single new species forms? Environmental pressures may cause populations to change over time or evolve. This is because an organism's ability to live to adulthood in its current environment will determine its reproductive success and ability to pass on its genes. But changes within a population can occur without creating a new species. At what point do scientists start thinking of a new name for a species?

Model 1 – Three Types of Selection

1. What variables do the graphs in Model 1 compare?
2. What are the three types of selection illustrated in the graphs in Model 1?
3. According to the graphs in Model 1, there is variation in the body mass in the original population. Using your knowledge of genetics, describe how this variation is possible.
4. Refer to graph A of Model 1.
 - a. How is the population that has experienced selection different from the original population?
 - b. **Fitness** is defined as the relative ability of an individual (or population) to survive, reproduce, and pass on genes. Which individuals in the original population appear to display better fitness?
 - c. As a group, propose some characteristics of the environment that could lead to the population changes illustrated in graph A.
5. Refer to graph B of Model 1.
 - a. How is the population that has experienced selection different from the original population?
 - b. Which individuals in the original population appear to display better fitness?
 - c. As a group, propose some characteristics of the environment that could lead to the population changes illustrated in graph B.
6. Refer to graph C of Model 1.
 - a. How is the population that has experienced selection different from the original population?
 - b. Which individuals in the original population appear to display better fitness?
 - c. As a group, propose some characteristics of the environment that could lead to the population changes illustrated in graph C.

The Yukaghir and the Yukaghirized Tungus Waldemar Jochelson, 1926 Natural Selection J. Phil Gibson, Terri R. Gibson, 2009 In his groundbreaking book *Natural Selection* Charles Darwin explained his theory that evolution is driven by adaptation of species to their environmental surroundings From the tiniest microbe to the largest whale all organisms have changed over vast expanses of time due to the forces of natural selection This new title in the Science Foundations series provides an overview of the processes and causes that drive natural selection and the principles that explain how it operates using numerous diverse organisms as examples *Natural Selection* promotes a solid understanding of how organisms change over the course of generations and how current biodiversity came to be *Adaptation and Natural Selection* George Christopher Williams, 2018-10-30 Biological evolution is a fact but the many conflicting theories of evolution remain controversial even today When *Adaptation and Natural Selection* was first published in 1966 it struck a powerful blow against those who argued for the concept of group selection the idea that evolution acts to select entire species rather than individuals Williams's famous work in favor of simple Darwinism over group selection has become a classic of science literature valued for its thorough and convincing argument and its relevance to many fields outside of biology Now with a new foreword by Richard Dawkins *Adaptation and Natural Selection* is an essential text for understanding the nature of scientific debate Introduction to Natural Selection Clifford Johnson, 1976 Genetic systems and fitness Evidence for selection The balanced polymorphism or the non neutral equilibria Selection coefficients in natural populations Varying fitness and the unit of selection Quantitative traits and the selection effect Selection in retrospect and prospect **Natural Selection** George C. Williams, 1992-10-01 In this work George C. Williams one of evolutionary biology's most distinguished scholars examines the mechanisms and meaning of natural selection in evolution Williams offers his own perspective on modern evolutionary theory including discussions of the gene as the unit of selection clade selection and macroevolution diversity within and among populations stasis and other timely and provocative topics In dealing with the levels of selection controversy he urges a pervasive form of the replicator vehicle distinction Natural selection he argues takes place in the separate domains of information and matter Levels of selection questions consequently require different theoretical devices depending on the domains being discussed In addressing these topics Williams presents a synthesis of his three decades of research and creative thought which have contributed greatly to evolutionary biology in this century *Evolution by Natural Selection*, 2006 **Natural Selection in the Wild** John A. Endler, 1986-04-21 Natural selection is an immense and important subject yet there have been few attempts to summarize its effects on natural populations and fewer still which discuss the problems of working with natural selection in the wild These are the purposes of John Endler's book In it he discusses the methods and problems involved in the demonstration and measurement of natural selection presents the critical evidence for its existence and places it in an evolutionary perspective Professor Endler finds that there are a

remarkable number of direct demonstrations of selection in a wide variety of animals and plants The distribution of observed magnitudes of selection in natural populations is surprisingly broad and it overlaps extensively the range of values found in artificial selection He argues that the common assumption that selection is usually weak in natural populations is no longer tenable but that natural selection is only one component of the process of evolution natural selection can explain the change of frequencies of variants but not their origins

The Statistics of Natural Selection on Animal

Populations Bryan F. J. Manly, 1985-09-19 In the concluding chapter of his famous book on the theory of evolution by natural selection Charles Darwin 1859 remarked that When the views entertained in this volume on the origin of species or when analogous views are generally admitted we can dimly foresee that there will be a considerable revolution in natural history This proved of course to be completely correct At present there is a great divergence of opinion about the general importance of natural selection in the evolutionary process Nevertheless biologists are on the whole united in their acceptance of the potential power of selection in changing populations Given this situation it is not surprising to find that many attempts to detect the effects of natural selection have been made since the time of Darwin This area of study has been called ecological genetics It involves the collection of data of various kinds and in many cases the development of special methods for analysing these data This book is a summary of methods for data analysis concentrating on those that are applicable to animal populations particularly wild populations

Natural Selection and Heredity Philip MacDonald

Sheppard, 1975 **On the Origin of Species Illustrated** Charles Darwin, 2021-01-20 Darwin addresses some of the flaws

in his theory of natural selection He tackles two major questions First if species have gradually descended from other species why do clearly defined separate species exist instead of numerous intermediate forms of species Second can natural selection really produce highly complex organs such as the eye from species lacking anything remotely similar to such complex organs To answer the first question Darwin argues that natural selection requires that intermediate varieties become extinct Since natural selection urges species to become perfectly adapted to their environments certain environments favor some characteristics and other environments favor others allowing species to diverge based on their separate environments The favored characteristics in these respective environments would become more advantageous than any intermediate characteristics causing the intermediate species to become extinct Darwin addresses the question of whether an intermediate species would exist in an intermediate geological area between the two different environments He argues that intermediate environments are so geographically small that intermediate species in those areas would not be able to reproduce sufficiently to perpetuate themselves and survive and would eventually become extinct Therefore we only see small numbers of intermediate species in these intermediate geographical zone Darwin is not as confident about the answer to his second question as he is about the answer to his first He admits that it is difficult to explain how new structures such as the wings of a bat are created when a species descends from one that lacks such structures He does give examples from other species in which modifications develop from existing structures instead of sprouting anew such as the species of flying squirrels with broad tails that allow them to parachute through the air a tail modified from existing tails in other squirrel species He also explains that scientists are unable to see a clear line of organ modification because of gaps in the development of these structures for example squirrel tails that are not yet fully adapted for flying These gaps come about when the intermediate species have become extinct Examples of explainable models such as the flying squirrel s tail can help an observer imagine the development of more complex organs such as the wings of the bat or the eye Over time gradual developments of structures and nerves become more complex with modifications until finally the most perfect eye organ develops Darwin compares the eye to a telescope Over time and through its development the telescope has become more and more advanced replacing older versions While the mechanism of change for the telescope is technological advancement for the eye it is natural selection Darwin also discusses the existence of undeveloped and useless organs In contrast to highly complex organs that are clearly products of natural selection undeveloped and useless organs indicate that some traits might have been advantageous at one point and eventually waned in importance over time Primarily Darwin argues that science cannot always assume the importance or unimportance of a particular variation Some organs transmitted to a species but useless to it may have been useful to a distant ancestor Moreover some modifications that seem important to us may not be important at all For example if only green woodpeckers existed scientists would assume that the color green was important to the woodpecker s survival However many different colors of woodpeckers exist so color must be a result of sexual

selection which is relatively unimportant for species survival The perpetuation of useless or random variations illustrates one of the principles of natural selection that selection of advantageous characteristics makes a species better than those before it but The Origin of Species by Means of Natural Selection Charles Darwin,1890
