

The Moose and Wolves of Isle Royale Lab

Background:

Isle Royale National Park is a remote island of Lake Superior and is part of the U.S. state of Michigan. Forty-five miles long and nine miles wide, it is the largest natural island in Lake Superior. Scientists have been studying the interactions of

wolves and moose at Isle Royale National Park since 1958. This is the longest continuous predator-prey study in the world. The prey to predator relationship of Isle Royale's moose and wolves has a direct effect on both species' populations. Wolves help stabilize the moose herd by preying on the old, young, and ill, while strong moose numbers allow for stable winter hunting for the wolves.

The prey to predator relationship of Isle Royale's moose and wolves has a direct effect on both species' populations. Wolves help stabilize the moose herd by preying on the old, young, and ill, while strong moose numbers allow for stable winter hunting for the wolves.

The Wolves: The gray wolf (Canis lupus), also known as the timber wolf, has been the

prevailing predator of Isle Royale National Park since its arrival to the island in the late 1940's. It is largely accepted that wolves arrived on Isle Royale by crossing an ice bridge that formed between the island and the Canadian mainland during the winter of 1948. Since this initial population of island wolves, the population has varied from 50 animals in 1980 to a low of two animals since 2018. Wolf population variation is driven by the availability of its

primary food source of older moose and calves, and the spread of canine diseases to the island. Furthermore, genetic inbreeding has led to physical deformities and has, at times, resulted in low productivity and survival.

The Moose: Moose (Alces alces) first arrived on Isle Royale in the early 1900s. Since that time, moose have become one of the iconic mammals of Isle Royale National Park. The moose population of Isle Royale has fluctuated over the years. Since 1980, the population has been as low as 500 animals and as high as 2,400. The fluctuation of population is directly connected to the vegetation and predators of the island. Higher numbers of moose on the finite land mass lead to over-browsing of island vegetation, which leads to population decrease due to winter starvation. The only island moose predator is the gray wolf. The fluctuation of wolf numbers impact the overall moose population.
